# Experimental Particle Physics PHYS6011
Southampton University Lecture 1

CMS Experiment at LHC, CERN
Data recorded: Thu Apr 5 05:47:32 2012 CEST
Run/Event: 190401 / 12545076
Lumi section: 75
Orbit/Crossing: 19495845 / 1347

Fergus Wilson, Email: Fergus.Wilson at stfc.ac.uk

Administrative Points

- 5 lectures:
  - Tuesday   12am: 24th April and 1st May (Murray/1065)
  - Wednesday 9am: 25th April and 2nd May (Murray/1039)
  - Thursday   2pm: 26th April (Nuffield/1083)
- Course Objectives, Lecture Notes, Problem examples:
  - http://www.hep.phys.soton.ac.uk/~stefano/PHYS6011/
  - http://hepwww.rl.ac.uk/fwilson/Southampton
- Resources:
  - K. Wille, "The Physics of Particle Accelerators"
  - D. Green, "The Physics of Particle Detectors"
  - K.Kleinknecht, "Detectors for Particle Radiation"
  - I.R. Kenyon, "Elementary Particle Physics" (chap 3).
  - Martin and Shaw, "Particle Physics"
  - Particle Data Group, http://pdg.lbl.gov

Syllabus – 5 lectures

1. ## Part 1 – Building a Particle Physics Experiment
   1. Accelerators and Sources
   2. Interactions with Matter
   3. Detectors
2. ## Part 2 – Putting it all together
   1. Looking for the top quark at the Tevatron
   2. Looking for the Higgs boson at the LHC (or what can you get for $10,000,000,000?)
Natural Units

- Natural Units:
  - Energy - GeV
  - Mass – GeV/c^2
  - Momentum – GeV/c
  - Length and time – GeV^{-1}
- Use the units that are easiest.
- 1 eV = 1.602 x 10^{-19} J
- Boltzmann Constant = 8.619 x 10^{-5} eV/Kelvin

$$\hbar = c = 1$$

$$E^2 = p^2 c^2 + m^2 c^4$$

$$\Rightarrow E^2 = p^2 + m^2$$

History of the Universe

Universe energy

$$T_{univ}(K) = 1.5 \times 10^{12} t^{-2/3} \quad t < 10^{11} \text{secs}$$

$$T_{univ}(K) = 2 \times 10^{10} t^{-1/2} \quad t > 10^{11} \text{secs}$$

Boltzmann constant, $k = 8.619 \times 10^{-5} \text{eV K}^{-1}$
- Time, energy (temperature) and distance are related:
  - High momentum : Small distance : High temperature : Early Universe

| Energy	Age (secs)	Temp. (K)	Observable Size
1 eV	10^{13}	10^4	10^6 Light Years
1 MeV	1	10^{10}	10^6 km
10 TeV	10^{-14}	10^{17}	10^{-2} mm

Natural Radioactivity

- First discovered in late 1800s (X-rays Becquerel 1896)
- Used as particle source in many significant experiments
  - Rutherford's 1906 experiment: elastic scattering $\alpha + N \rightarrow \alpha + N$
  - Rutherford's 1917 experiment: inelastic scattering $\alpha + N \rightarrow p + X$
- Common radioisotopes include
  - ^{55}Fe: 6 keV γ, $\tau_{1/2}$ = 2.7 years (discovered?)
  - ^{90}Sr: 500 keV β, $\tau_{1/2}$ = 28.9 years (1790)
  - ^{241}Am: 5.5 MeV α, $\tau_{1/2}$ = 432 years (1944)
  - ^{210}Po: 5.41 MeV α, $\tau_{1/2}$ = 137 days (1898)
- Radioactivity of food
  - Bananas : 3500 pCi/Kg
  - Beer: 400 pCi/Kg
- Easy to control, predictable flux but low energy
- Still used for calibrations and tests

Cosmic Rays

- History
  - 1912: First discovered (Hess)
  - 1927: First seen in cloud chambers
  - 1962: First 10^{20} eV cosmic ray seen
- Low energy cosmic rays from Sun
  - Solar wind (mainly protons)
  - Neutrinos
- High energy particles from sun, galaxy and perhaps beyond
  - Primary: Astronomical sources.
  - Secondary: Interstellar Gas.
  - Neutrinos pass through atmosphere and earth
  - Low energy charged particles trapped in Van Allen Belt
  - High energy particles interact in atmosphere.
  - Flux at ground level mainly muons: 100-200 s^{-1} m^{-2}
- Highest energy ever seen $\sim 10^{20}$eV
Cosmic Rays

$$I_N(E) \approx 1.8 E^{-2.7} \frac{nucleons}{cm^2 s\ sr\ GeV} \qquad E < 100\,TeV$$
**Figure 24.4:** Spectrum of muons at $\theta = 0°$ (♦ [29], ■ [34], ▼ [35], ▲ [36], × and + [31], and $\theta = 75°$ ◇ [37]) .

Galactic Sources

Intergalactic Sources?

GZK cutoff 10^{20} eV. Should be impossible to get energies above this due to interaction with CMB unless produced nearby => Black Holes?

LHC

Cosmic Ray Experiments

6cm

- Primary source for particle physics experiments for decades

- Detectors taken to altitude for larger flux/higher energy

- Positron (1932) and many other particles first observed

Which direction is the e⁺ moving (up or down)?

Is the B-field in or out of the page?

Modern experiments include:

- Particle astrophysics
  - Space, atmosphere, surface, underground

- Neutrino
  - Solar, atmospheric

- "Dark Matter" searches

Still useful for calibration and testing
1912 CTR Wilson Cloud Chamber

Cosmic Rays - Pierre Auger Project

Surface Array
1600 detector stations
1.5 km spacing
3000 km²

Fluorescence Detectors
4 Telescope enclosures
*6 Telescopes per enclosure*
24 Telescopes total

**60 km**
Active Galactic Nuclei and cosmic rays

Highest energy cosmic rays seem to be associated with Active galactic nuclei but are they? www.auger.org

Dark Energy and Dark Matter

- Most of the Universe is invisible.
- Dark Energy:
  - Exerts a negative pressure on the Universe
  - Increases the acceleration of the galaxies.
- Dark Matter:
  - Just like ordinary matter but not visible (does not give off light).
- 1: Baryonic Dark Matter
  - ~2% of the Universe
  - MACHOS, dwarf stars, etc…
- 2: Non-Baryonic Dark Matter
  - ~20% of the Universe
  - Hot (neutrinos) and Cold (WIMPS, axions, neutralinos).
  - Expected to be mostly Cold

Atoms 4.6%
Dark Matter 23%
Dark Energy 72%
TODAY

Neutrinos 10 %
Photons 15 %
Atoms 12%
Dark Matter 63%
13.7 BILLION YEARS AGO
(Universe 380,000 years old)

Observed

Predicted

Velocity

Distance

Rotation Velocity $v(r) = \sqrt{\dfrac{M(r)}{r}}$

Outside Galaxy $v(r) \propto \dfrac{1}{\sqrt{r}}$

Dark Matter - DAMA

2-4 keV

DAMA/LIBRA ≈ 250 kg   (0.87 ton×yr)

http://arxiv.org/abs/1002.1028
1. **As the earth goes round the sun, its velocity relative to the galaxy changes by +/-30 km**

2. **Look for nuclear recoil in NaI as nucleus interacts with "dark matter" particle.**

3. **Expect to see a change in the rate of interactions every six months**

4. **But is there really a pattern? and is it really dark matter?**
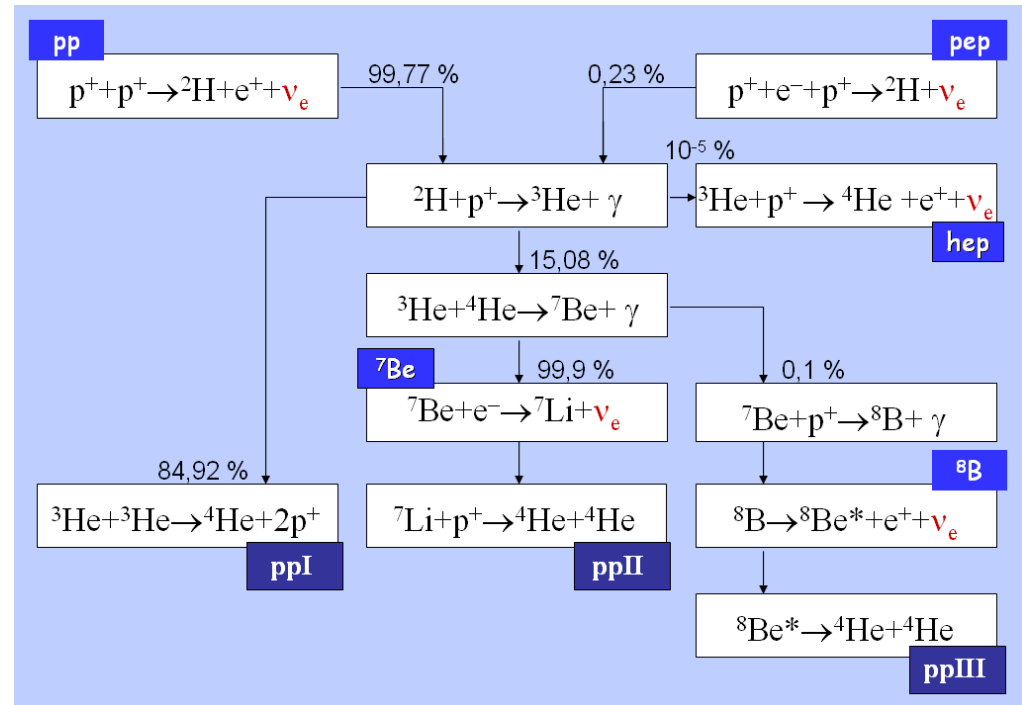

Neutrinos – Nuclear Reactors and the Sun

- Reactors – Nuclear Fission
- Sun – Nuclear Fusion
- But still weak interactions. Well understood.
- Huge fluxes of MeV neutrons and electron neutrinos.
- But low energy.
- First direct neutrino observation in 1955.

Neutrino density at Earth $\sim 5 \times 10^6\, cm^{-2} s^{-1}$

Mean free path d:

$$d \approx \frac{u}{\sigma\rho} = \frac{1.66 \times 10^{-27}\, \text{kg}}{\left(10^{-47}\, \text{m}^2\right)\left(\rho\, \text{kg/m}^3\right)}$$

$$\Rightarrow d_{\text{water}} = 18 \text{ light years}$$

pp

$$p^+ + p^+ \rightarrow {}^2H + e^+ + \nu_e$$

99,77 % 0,23 %

pep

⁷Be

99,9 % 0,1 %

$$^7Be + e^- \rightarrow {}^7Li + \nu_e$$

$$^7Be + p^+ \rightarrow {}^8B + \gamma$$

⁸B

84,92 %

$$^3He + {}^3He \rightarrow {}^4He + 2p^+$$

$$^7Li + p^+ \rightarrow {}^4He + {}^4He$$

$$^8B \rightarrow {}^8Be^* + e^+ + \nu_e$$

ppI **ppII**

$$^8Be^* \rightarrow {}^4He + {}^4He$$

ppIII

Neutrino Oscillation

$$|\nu_\alpha\rangle = \sum_{i=1}^{3} U_{\alpha i} |\nu_i\rangle \qquad P_{\alpha \to \beta} = \left| <\nu_\beta | \upsilon_\alpha(t) > \right|^2$$

α = neutrino with definite flavour (e,μ,τ)

i = neutrino with definite mass (1,2,3)

$U_{\alpha i}$ = PMNS mixing matrix

$$P_{\nu_\alpha \to \nu_\beta} = \sin^2(2\theta)\sin^2\left(1.267 \frac{\Delta m^2 L}{E} \frac{GeV}{eV^2 km}\right)$$

$$\Delta m_{12}^2 = \Delta m_{solar}^2 = (8.0^{+0.6}_{-0.4}) \times 10^{-5} eV^2$$

$$\theta_{12} = \theta_{solar} = (33.9^{+2.4}_{-2.2})^o$$

$$\Delta m_{23}^2 = \Delta m_{atm}^2 = (2.4^{+0.6}_{-0.5}) \times 10^{-3} eV^2$$

$$\theta_{32} = \theta_{atm} = (45 \pm 7)^o$$

$$\theta_{13}, \Delta m_{13}^2 = unknown$$

- Neutrinos "Oscillate":
  - Can change from one type to another.
  - Implies ν have mass.
  - Oscillation experiments can only measure difference in squared mass Δm^2

Daya Bay (March 8th 2012)

- **3 sets of detectors surrounded by 6 civilian nuclear reactors**

- **Look for electron anti-neutrinos**

$$P_{\alpha \to \alpha} \approx 1 - \sin^2 2\theta_{13} \sin^2 (1.267 \Delta m_{13}^2 L / E)$$

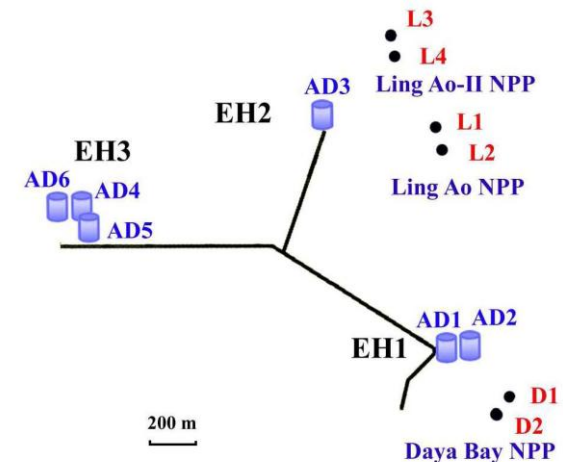

FIG. 1. Layout of the Daya Bay experiment. The dots represent reactors, labeled as D1, D2, L1, L2, L3 and L4. Six ADs, AD1–AD6, are installed in three EHs.

- **Result:** $\sin^2 \theta_{13} = 0.092 \pm 0.016 (stat) \pm 0.005 (syst)$
  - Implies value > 0

  RENO (South Korea) has also reported results (3-Apr-2012)

Particle Sources

Want intense monochromatic beams on demand:

1. Make some particles
   - Electrons: metal + few eV of thermal energy
   - Protons/nuclei: completely ionise gas
2. Accelerate them in the lab
+ve

-ve

e^-

K.E. = e×V

V

Creating Electrons

- Triode Gun
- Current: 1 A
- Voltage: 10 kV
- The grid is held at 50V below cathode (so no electrons escape).
- When triggered, grid voltage reduced to 0V. Electrons flow through grid.
- Pulse length: ~1ns

Creating Positrons

pre-accelerator
(125-400 MeV)

booster linac
(cryomodules to boost energy to 5 GeV)

~147 GeV e⁻   target

150 GeV e⁻

# Creating Protons – PIG (Penning Ion Gauge)

Hydrogen gas bottle

Tevatron

- Ion source (e.g. H_2) introduced as a gas and ionised.
- Magnetic field 0.01T perpendicular to E-field causes ions to spiral along B-field lines.
- Low pressure needed to keep mean-free path long (10^{-3} Torr).
- Modern methods are more complicated.
- http://www-bdnew.fnal.gov/tevatron/

Anti-Proton Production at CERN

© 1996, T.Sefzick, Forschungszentrum Jülich, Germany

Protons are accelerated in a linear accelerator, booster, and proton synchroton (PS) up to 27 GeV. These protons hit a heavy target (Beryllium). In the interaction of the protons and the target nuclei many particle-antiparticle pairs are created out of the energy, in some cases proton-antiproton pairs. Some of the antiprotons are caught in the antiproton cooler (AC) and stored in the antiproton accumulator (AA). From there they are transferred to the low energy antiproton ring (LEAR) where experiments take place.

DC Accelerators – Cockcroft Walton

How it works
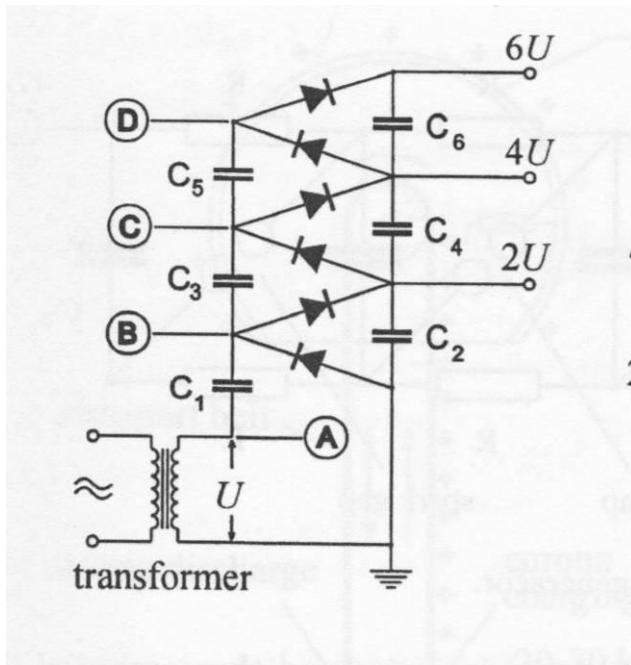

Cockcroft and Walton's Original Design (~1932)

Fermilab's 750kV Cockroft-Walton

Figure 1.2

- DC accelerators quickly become impractical
- Air breaks down at ~1 MV/m

DC Accelerators – Van der Graff

accelerating gap

Precision Graphics

Cyclotrons - Variations

- **Cyclotron limitations:**
  - Energy limit is quite low: 25 MeV per charge
  - Non-relativistic velocity v < 0.15c
- **Alternatives:**
  - Syncro-cyclotron
    - Keep magnetic field constant but decrease RF frequency as energy increases to compensate for relativistic effects.
  - Iso-cyclotron
    - Keep RF frequency the same but increase the radial magnetic field so that cyclotron frequency remains the same:
    - Can reach ~600 MeV

 $$\omega = \frac{qB(r(E))}{m(E)} = const.$$

  - Synchrotron
   - For very high energies. See later…

Linear Accelerators
For energies greater than few MeV:

- Use multiple stages
- RF easier to generate and handle
- Bunches travel through resonant cavities
- Spacing and/or frequency changes with velocity
- Can achieve 10MV/m and higher
- 3km long Stanford Linac reached 45 GeV
- 30km Linear Collider would reach 250 GeV.
Superconducting Cavities & Klystron

Early Warning Radar

SLAC Klystron Hall
Synchrotrons

- *p (GeV/c) = 0.3 q B R*
- Cyclotron has constant *B*, increasing *R*
- Increase *B* keeping *R* constant:
  - variable current electromagnets
  - particles can travel in small diameter vacuum pipe
  - single cavity can accelerate particles each turn
  - efficient use of space and equipment
- Discrete components in ring
  - cavities
  - dipoles (bending)
  - quadrupoles (focusing)
  - sextuples (achromaticity)
  - diagnostics
  - control
$$mv^2 = Bqv$$

$$\omega = \frac{v}{r} = \frac{Bq}{m}$$

$$f = \frac{Bq}{2m\pi}\frac{m_0}{m_0 + T}$$

Synchrotron Radiation

- Accelerated charges radiate
- Average power loss per particle:
- Quantum process → spread in energy
- For a given energy ~ 1/mass^4
  - (this comes from γ in the power loss equation)
- Electron losses much larger than proton
  - High energy electron machines have very large or infinite R (i.e. linear).
- Pulsed, intense X-ray source may be useful for some things....

$$\text{Power loss (Watts)} = \frac{1}{6\pi\varepsilon_0}\frac{e^2 a^2}{c^3}\gamma^4 \quad a = \frac{v^2}{R} \quad \gamma = \frac{E}{m_o}$$

$$\Rightarrow \text{Electron Power Loss per turn} = \frac{8.85\times10^{-5}E^4}{R} \text{ MeV/turn}$$

E in GeV, R in km.

$$\Rightarrow \text{Proton Power Loss per turn} = \frac{7.78\times10^{-3}E^4}{R} \text{ keV/turn}$$

E in TeV, R in km.

g
Fixed Target Experiments

Beam incident on stationary target

- Interaction products have large momentum in forward direction

- Large "wasted" energy $\Leftrightarrow$ small $\sqrt{s}$

- Intense beams/large target $\Rightarrow$ high rate

- Secondary beams can be made.
$$p_1 = (E_1, \bar{p}_1) \quad p_2 = (E_2, \bar{p}_2) \quad E^2 = p^2 + m_0^2$$

Centre of Mass energy squared $s = E_{cm}^2 = (p_1 + p_2)^2$

$$\Rightarrow E_{cm} = \left[(E_1 + E_2)^2 - (\bar{p}_1 + \bar{p}_2)^2 \right]^{1/2}$$

Minos Hall
Minos Near Detector

700 m

700 km
- Fermilab sends a ν_μ beam to Minnesota
- Looking for oscillations
- Detector at bottom of mine shaft

Colliders

- Incoming momenta cancel
- $\sqrt{s} = 2E_{beam}$
- Same magnetic field deflects opposite charges in opposite directions $\Rightarrow$ *Antiparticle accelerator for free!*
  - particle/antiparticle quantum numbers also cancel
- *Technically challenging*
Event Rate $R = L\sigma$

Current $I_i = n_i e f N_b$

Luminosity $= f \dfrac{n_1 n_2}{4\pi \sigma_x \sigma_y} = \dfrac{I_1 I_2}{4\pi f N_b e^2 f \sigma_x \sigma_y}$

frequency

bunch size

#bunches

Different Colliders

- **_p anti-p_**
  - energy frontier
  - difficult to interpret
  - limited by anti-p production
  - *SPS, Tevatron*

- **_p p_**
  - high luminosity
  - energy frontier
  - *LHC*

- **_μ+ μ-_**
  - some plans exist

- $e^+ e^-$
  - relatively easy analysis
  - high energies difficult
  - *LEP, PEP, ILC...*

- **_e p_**
  - proton structure
  - *HERA*

- *ion ion*
  - quark gluon plasma
  - *RHIC, LHC*

- *ν ν*
  - Muon Collider !!!

Complexes

- Synchrotrons can't accelerate particles from rest
- Designed for specific energy range, normally about factor of 10
